Abstract (100 words): This manuscript reports the results of a study that investigated the effects of a 12-week, low-intensity, resistance training program on the muscle strength and endurance of older adults. The study was conducted in a laboratory setting and involved 20 participants aged 65 and older. The participants were randomly assigned to either a control group or an exercise group. The exercise group performed a series of resistance exercises three times per week for 12 weeks. The control group did not perform any exercises. The results of the study showed that the exercise group had significantly greater muscle strength and endurance than the control group at the end of the 12-week period. The findings of this study suggest that a low-intensity, resistance training program can be an effective way to improve muscle strength and endurance in older adults.

How would you hypothetically testing and prediction question:

There is an important testing question: Is there a significant difference in the proportion of men and women who are smokers? This drug experiment cannot tell the significance difference in smoking rates, but it does give information for the proportion of smokers and of nonsmokers among men and women who are in the study. The fact that the proportion of smokers is the same among men and women is unlikely, due to the fact that men are generally heavier smokers than women, and men have a higher smoking rate and are more likely to die from smoking-related diseases. The fact that the proportion of smokers is the same among men and women is unlikely, due to the fact that men are generally heavier smokers than women, and men have a higher smoking rate and are more likely to die from smoking-related diseases. The fact that the proportion of smokers is the same among men and women is unlikely, due to the fact that men are generally heavier smokers than women, and men have a higher smoking rate and are more likely to die from smoking-related diseases.

[illegible][illegible][illegible][illegible][illegible][illegible][illegible]

Figure 1: Percentage of respondents who used various products in the past 12 months, categorized by gender (Male and Female). The chart compares 'Used' and 'Not Used' for each product.

Gender	Product	Used (%)	Not Used (%)
Male	Alcohol	~10	~90
	Drugs	~10	~90
	Heroin	~10	~90
	Heroin/Alcohol	~10	~90
Female	Alcohol	~10	~90
	Drugs	~10	~90
	Heroin	~10	~90
	Heroin/Alcohol	~10	~90

Hypothesis Testing

Visualizing what your data tells you is not enough! You may split portions of your data into different cells, think the data is informative, and then find your results are uninformative.

```

# Hypothesis testing in R: simple case: proportions
# Example: Is the proportion of red flowers in the population
# equal to 0.5? (H0: p = 0.5) vs. H1: p != 0.5
# Data: 100 flowers, 55 are red
n = 100
x = 55
# Test statistic: Z = (x - np) / sqrt(np(1-p))
# where p = 0.5
Z = (x - np) / sqrt(np(1-p))
# P-value: 2 * (1 - pnorm(abs(Z)))
p_value = 2 * (1 - pnorm(abs(Z)))
# Decision: if p_value < 0.05, reject H0

```

Device Type	Smartphone (%)	Tablet (%)	Desktop/Laptop (%)
Smartphone	~85	~10	~5
Tablet	~15	~85	~0
Desktop/Laptop	~10	~10	~80
